divisional application to the application mentioned
under INID code 62.

(54) **Surgical instrument actuating member and system for connecting different types of instruments**

(57) The surgical instrument system disclosed is particularly useful for endoscopic procedures. In the preferred embodiment, a hemostatic clip applicator can be directly connected to a trigger assembly or indirectly connected to the trigger assembly through the use of an extension. The connection between the extension and the clip applicator is secured to prevent accidental release during the procedure. The applicator receives a longitudinal input and translates the input into relative component motion through the use of gearing to apply the clips.

EP 0 755 655 A2

Description

Field of the Invention

The field of the invention relates to surgical instruments, for example those that can be used in endoscopic surgery with the emphasis on applying hemostatic clips.

Background of the Invention

Endoscopic surgery frequently requires the application of hemostatic clips or the use of other instruments which can ligate, grab or rip for a variety of purposes. Several significant characteristics of such instruments need to be simplicity in construction, reliability in operation, as well as low cost. Components that come into contact with internal organs in the body must also be effectively sterilized. Alternatively, the construction needs to be sufficiently economical to allow disposability of contaminated components. The layout of the instrument needs to be such as to give the surgeon good feedback during the procedure as to allow as much control as possible while using the instrument. If component systems are used, it is important to have them securely attached to each other to avoid disconnection during the procedure which could jeopardize the patient's condition should detachment occur during a procedure.

Surgical instruments that are adaptable to more than one procedure are preferred. A versatile system of surgical instruments which allows different types of instruments to be used in conjunction with a given actuating system is also a desirable feature.

In the past, various surgical instruments have been developed which address some, but not all of these needs. Some of the problems in addressing many of these needs is that a solution to one of such needs works at cross purposes to another. The result in the past has been fairly complex instruments which have adequately addressed one or two of such design requirements while compromising on the others. Hemostatic clip applicators of varying complexity are known in the art as exemplified by U.S. Patent Nos. 5,049,152; 5,084,057; 5,100,420; 5,163,945; 4,496,090; 3,675,688; and Reissue 28,932. Some of these patents reveal the use of a trigger grip to actuate a rod by which motion is transferred directly to an operating component for accomplishing the purpose of the instrument. Typical of such devices is U.S. Patent No. 4,759,364 which illustrates pincers that are rod actuated. Yet, other clip applicators use a scissor grip and linkage in combination with spring forces to accomplish the clip application. U.S. Patent No. 5,104,395 illustrates this principle. Other clip applicators that work in a similar fashion employ a ratcheted counterwheel, wherein, every time a clip is applied, the wheel is rotated giving a visual display to the surgeon of the number of clips remaining. This type of clip applicator is shown in U.S. Patent No. 5,047,038. Alterna-

tively, to a ratcheted wheel indicating the number of clips remaining, transparent covers, such as shown in U.S. Patent No. 5,104,395 have also been used to allow the surgeon to see how many clips remain in the stack.

GB Patent Application GB-A-2162782 describes a surgical stapler in which a handle grip, when squeezed, moves forward a crimp bar which cams clip-forming jaws together. About two thirds of the way through the movement, a system of levers, gears and racks beneath the grip pulls back a clip injector in the crimp bar. Release of the grip retracts the crimp bar and moves the injector forwards.

Outside the medical field, staplers have been used to hold objects together, such as in upholstery construction. Typical of such staplers is U.S. Patent No. 2,296,493 illustrating a hand-operated stapling machine using a rack and pinion linkage with regard to the staple feeding operation.

The apparatus specifically described herein has the objectives of providing a simple and economical construction that gives good feedback in the surgeon's hand as to the procedure being conducted. A system of components is provided which has reusable and disposable features. The connection system between the components gives certainty of fixation, thereby eliminating the risk of accidental disconnection during a procedure within the body. The system also provides for adjustability for using clips of various lengths or widths. The clip applicator also provides a feature to ensure sufficient jaw opening prior to feeding of the next successive clip. This avoids the hazards of jamming.

Summary of the Invention

The invention provides a surgical instrument assembly comprising:

- an actuating member formed to be grasped by hand; and
- an instrument having a body;
- said actuating member having a housing which accepts an end of said instrument body.

The surgical instrument system disclosed is particularly useful for endoscopic procedures. In the preferred embodiment, a hemostatic clip applicator can be directly connected to a trigger assembly or indirectly connected to the trigger assembly through the use of an extension. The connection between the extension and the clip applicator is secured to prevent accidental release during the procedure. The applicator receives a longitudinal input and translates the input into relative component motion through the use of gearing to apply the clips.

Other preferred features are set out below in the dependent claims.

Brief Description of the Drawings

Figure 1 is an exploded view showing the assembly of the components of a preferred clip applicator according to the invention.

Figures 2A-2C are partial cutaway top views of the applicator as shown in Figure 1 in a fully assembled condition and further illustrating the idler feature of the feeder.

Figure 3 is the view at section lines 3-3 shown in Figures 2A-2C.

Figures 4A-4F are sectional elevational views of the applicator with the feeder in various positions.

Figure 5 illustrates the extension member with a partial cutaway showing its operation.

Figure 6 is a section view of the extension member of Figure 5.

Figure 7 is the view along section 7-7 shown in Figure 6.

Figure 8A shows the alignment of the applicator to the extension;

Figure 8B shows insertion of the extension into the applicator;

Figure 8C shows further extension of the extension over the applicator;

Figure 8D illustrative relative rotation as between the applicator and the extension; and

Figure 8E shows the secured position between the applicator and the extension.

Figure 9 is the operating mechanism in an open position.

Figure 10 is the operating mechanism in a closed position.

Figure 11A illustrates a partial cutaway view of an alternative embodiment of a stapler showing a formed staple;

Figure 11B is the stapler of Figure 11A in a different position with the staple ejected; and

Figure 11C is an elevational view of the alternative embodiment shown in Figure 11A in partial cutaway.

Detailed Description of the Preferred Embodiment

The apparatus A of the present invention is an instrument, or a variety of instruments, useful for endoscopic or less invasive surgeries. The major components in the preferred embodiment are a clip applicator generally referred to as 10 (see Figure 1); an extension member 12 (see Figure 5); and an actuator 14 (see Figure 9). These components can be used altogether or, alternatively, the actuator 14 can be applied directly to the clip applicator 10. Alternatively, actuator 14 can be used with other types of surgical instruments which are operable by longitudinal input movement which creates a relative movement in response to an input force to accomplish a surgical procedure.

Referring now to Figure 1, the details of the construction and operation of the clip applicator 10 will be

described. A cover tube 16 holds bottom housing 18 and top cartridge 20 together. A pusher spring 22 is connected at its distal end to top cartridge 20 and at its proximal end to pusher 24. The proximal end of pusher 24 has a pushing surface 26 which is a surface conforming to the clip 28. In the preferred embodiment, a series of clips 28 can be stacked end-to-end in front of pushing surface 26; however, an applicator that applies one or more clips in sequence can be employed. The clips 28 rest on a feeder 30 as does pusher 24. The distal end of feeder 30 comprising a pushing surface 32 which, like pushing surface 26, conforms to the body shape of the clips 28 for the purpose of further advancing a clip as will be described below. The feeder 30 rests on cartridge floor 34. It should be noted that the assembly of the top cartridge 20, pusher spring 22, pusher 24, clips 28, feeder 30 and cartridge floor 34 can be assembled as subassembly. The cartridge floor 34 has a plurality of cutouts 36 on both sides of its longitudinal centerline. A plurality of posts 38 conform to the shape of cutouts 36 and align the top cartridge 20 and the cartridge floor 34 to bottom housing 18.

Vessel stop 40 has a plurality of cutouts 42 which are aligned with cutouts 44 on jaw 46. Vessel stop 40 prevents vessel from dislodging clip 28. Jaw 46 and vessel stop 40 are put together by aligning openings 42 and 44 onto posts 48 in bottom housing 18 after initially slipping the assembly of vessel stop 40 and jaw 46 through the distal end 50 of closure member 52. Jaw 46 has a pair of opposed tapered surfaces 54 at the distal end of an elongated slot 56. Mounted distally to the tapered surfaces 54 are crimping members 58 and 60. Closure member 52 is mounted within housings 18 and 20 and can translate responsive to a force input. A spring 62 connected at its distal end to tab 64 on closure member 52 and on its proximal end to post 66 on bottom housing 18 applies a force in the proximal direction to closure member 52. Slot 68 on closure member 52 accommodates spring 62. Posts 48 in bottom housing 18 extend through openings 42 and 44 and into slot 70 on closure member 52, thereby, in the preferred embodiment, limiting the amount of travel of closure member 52 in the distal direction. While a transition 72 is illustrated to accommodate the placement of the floor 34 over the closure member 52, the apparatus A of the present invention encompasses a closure member that does not necessarily include such a transition surface 72.

Referring now to Figures 2A-2C and 3, bottom housing 18 accommodates spindle 74 of gear 76. Gear 76 is a compound gear, which, in the preferred embodiment, is really two gears parallel to each other supported by spindle 74. In the preferred embodiment, gear 76 has an upper gear 78 and a lower gear 80. The diameters and hence the number of teeth in gears 78 and 80 are different. The dictates of design determine the ratio of teeth and diameters of the gears 78 and 80 based on the degree of relative movement desired for the application. Different sized clips can be accommodated in the same applicator 10 by varying this ratio. While gears are

recited, other motion reversing mechanisms can be employed. This includes pulley systems as well as wheels that rely on friction to reverse motion, as well as lever assemblies. Spindle 74 may be motorized or powered to accomplish reverse motion as opposed to an input force to closure member 52 or to feeder 30 which are preferably stacked. Referring to Figures 1 and 2A-2C, it can be seen that feeder 30 has a plurality of teeth 82 which are visible in Figure 1 due to a partial cutaway. Another view of teeth 82 is illustrated in Figures 2A-2C. As indicated in Figures 2A-2C and 3, teeth 82 engage substantially in the same plane with upper gear 78. Lower gear 80 is substantially in the same plane as idler rack 84. Idler rack 84 has a plurality of teeth 86 which engage lower gear 80. As seen in Figures 1 and 3, teeth 82 face teeth 86 on opposite sides of longitudinal axis of cover tube 16 with teeth 82 being in a higher plane than teeth 86 of idler rack 84. Mounted to the distal end of idler rack 84 is rack latch 88. Rack latch 88 has a cantilevered and inclined finger 90. As shown in Figures 2A-2C, finger 90 extends obliquely toward teeth 82 but is in a plane below such teeth such that upon distal movement of closure member 52, finger 90 skips over tab 92 as shown by comparing the top two views of Figures 2A-2C. When the closure member 52 moves in the proximal direction, a tab 94, which extends downwardly from the closure member parallel to its longitudinal axis, engages finger 90 and moves it up and over tab 92. The proximal end of idler rack 84 is connected to spring 96 with the proximal end of spring 96 secured to the bottom housing 18, as shown in Figure 1. The underside of closure member 52 has a notched area 98, as shown in Figure 1. Idler rack 84 has a shoulder 100 and an opposed shoulder 102. The notched area 98 in closure member 52 is defined by shoulders 104 and 106 (see Figure 1). The distance between shoulders 100 and 102 is smaller than the distance between shoulders 104 and 106 for a purpose which will be described below. Closure member 52 has a notched surface 108 to accommodate the feeder 30, as shown in the section view of Figure 3.

The operation of the clip applicator 10 is initiated by a force supplied to closure member 52. Prior to getting into the details of the operation of clip applicator 10, the operation of the extension member 12 and actuator 14 will be described. Figure 1 illustrates that the top cartridge 20 has an L shaped slot 110, which has a longitudinal component 112 and a radial component 114. While only one L shaped slot is shown in Figure 1, those skilled in the art can appreciate that a plurality of such L shaped slots 110 can be employed for the purposes of securing the clip applicator 10 either to the extension member 12 or the actuator 14. The actuator 14 in its two positions is illustrated in Figures 9 and 10. A handle 116 is mounted to a trigger 118 at pin 120. Trigger 118 has an extension tab 122 which extends into barrel 124. At least one pin 126 extends into barrel 124 and holder 128. Pin or pins 126 are mounted into a position so as to engage L shaped slot 110 (see Figure 1) of top car-

tridge 20. Through a bayonet-type mounting, the clip applicator 10 is longitudinally inserted so that longitudinal component 112 of L shaped slot 110 passes by pin or pins 126. The clip applicator 10 is then rotated to move the radial component 114 of L shaped slot 110 past pin or pins 126 to secure the attachment. It should be noted that there is a pin 126 for each L shaped slot 110 provided in top cartridge 120.

Tab 122 extends into barrel 124 and engages a groove 130 on sleeve 132. A dowel 134 fixes rod 136 to sleeve 132. A knob 138 is rotatably mounted on its central axis to barrel 124 and is retained against longitudinal movements by virtue of pin 140 extending into groove 142 of sleeve 132. When the clip applicator 10 is inserted into barrel 124 and engaged on pins 126, rod 136 is aligned with closure member 52. As a result, moving the trigger from the position shown in Figure 9 to the position shown in Figure 10, translates sleeve 132 and rod 136 distally, which, in turn, begins distal movement of closure member 52. It should be noted that the connection, as illustrated in Figures 9 and 10, is not a fail-safe connection in the sense that rotation of the clip applicator 10 can result in disengagement from actuator 14. However, without the use of extension member 12, the procedure being done with the clip applicator 10 connected directly to the actuator 14 is primarily not very deep within the body of the patient; therefore, making the security of the attachment a lesser concern than in a situation involving an endoscopic procedure. However, the connection, as previously described, at the distal end of barrel 124 involving pins 126 can be fashioned differently along the lines as will be described with reference to Figures 5-7 so as to provide a fail-safe connection if the clip applicator 10 is connected directly to the actuator 14.

It should be noted that the trigger 118 returns from its closed position shown in Figure 10 to its open position shown in Figure 9 by virtue of spring 201.

At times it may be desirable to use the apparatus A of the present invention in an endoscopic procedure. When doing so, the extension member 12 becomes an additional advantage. Referring to Figure 5, the outer assembly of the extension member 12 is illustrated. An L shaped slot 144 is at the proximal end of extension member 12 and is for the same purpose as previously described in L shaped slot 110. L shaped slot 144 is disposed in guide 146 which extends the substantial length of extension member 12. Concentrically mounted to guide 146 is extension rod 148. Also, concentrically mounted with respect to guide 146 is tube 150. Tube 150 is secured to guide 146 by pin 152 which extends radially through guide 146, tube 150, and fixed cuff 154. Extension rod 148 has a longitudinal slot 156 to allow extension rod 148 to translate with respect to pin 152 with pin 152 being a distal travel stop as shoulder 158 engages pin 152. The position of extension rod 148 corresponds to the open position of actuator 14, as shown in Figure 9. When the actuator 14 is assembled to the extension member 12, rod 136 and extension rod 148

are in alignment for tandem movement. As shown in Figure 7, guide 146 has a pair of opposed slots 160 and 162. Slides 164 and 166 are disposed in slots 160 and 162, respectively. A pin 168 extends through slide cuff 170 and into slide 164. Similarly, a pin 172 extends through slide cuff 170 and into slide 166. It should be noted that the tube 150 has slots 174 and 176 to allow the assembly of slide cuff 170 and slides 164 and 166 to move with respect to guide 146. A spring 178 biases slide cuff 170 distally as a result of it bearing on fixed cuff 154. One pin 180 for each L shaped slot 110 mounted to clip applicator 10 is disposed at the distal end of extension member 12.

The L shaped slots 110 on the clip applicator 10 are preferably identical to the L shaped slots on the extension 12 for interchangeability with actuator 14. Likewise, the pins 180 on extension 12 are preferably identical to pins 126 on the actuator 14.

All of the components of extension member 12 having been described, the method of securing the clip applicator 10 will now be described. As shown in Figure 8, the longitudinal component 112 of L shaped slot 110 is aligned with pin 180. The clip applicator 10 is advanced proximally until longitudinal slot 112 registers with pin 180, as shown as the second step in the sequence of motions in Figure 8. The next step requires further advancement of clip applicator 10 in the proximal direction until pin 180 bottoms in longitudinal slot 112. As the third step occurs, the slides 164 and 166 are pushed proximally from their position in the second step, which, in turn, translates slide cuff 170 and compresses spring 178. In the fourth step, the applicator 10 is rotated so that radial component 114 of L shaped slot 110 moves past pin 180. As the rotation progresses, ultimately the longitudinal component 112 becomes aligned with a corresponding slide 164 or 166. At that time, the force of spring 178 acts on slide cuff 170, which, through pins 168 and 172, forces slides 164 and 166 distally until they are registered in longitudinal component 112. The force of spring 178 then retains the connection between extension member 12 and applicator 10 such that rotation is prevented and there is no accidental disconnection. If disconnection is desired, a force in the proximal direction must be applied to slide cuff 170 to overcome the force of spring 178 and translate slides 164 and 166 proximally to take them out of register with longitudinal component 112 of L shaped slot 110. At that time, rotation in the opposite direction of the previous rotation reverses the steps shown in Figure 8 and allows for disconnection between the extension member 12 and the clip applicator 10. The extension member 12 can be made of any desirable materials and, as previously stated, may have a similar connection at its proximal end, as illustrated for its distal end. This type of fail-safe connection could be positioned on the proximal end of extension member 12 in lieu of L shaped slot 144. Accordingly, depending on the need, a fail-safe connection can be provided in the connection between the actuator 14 and the extension member 12,

as well as between the extension member 12 and the clip applicator 10 and between the actuator 14 and the clip applicator 10.

Those skilled in the art will appreciate that the actuator 14 is reusable as can be extension member 12.

It should be noted that during the procedure, the surgeon can reorient the position of crimping members 58 and 60 (see Figure 1) by applying a rotational force to knob 138 (see Figure 9). A rotational force applied to knob 138 is transmitted through sleeve 132, dowel 134, into holder 128 and pins 126, which causes the clip applicator 10, or the combination of clip applicator 10 and extension member 12, to rotate in response to rotation of knob 138.

Referring now to Figures 1-4, the operation of the clip applicator 10 will now be described in detail. The process of positioning and feeding the clips 28 will be described by reference to Figures 4A-4F. In Figure 4A, the feeder 30 is distally extended so that a clip 28 is between crimping members 58 and 60. Since the views of Figures 4A-4F are in sections, only crimping member 58 is illustrated. In the second step illustrated in Figure 4B, the feeder 30 has been retracted thus allowing the pusher 24 (see Figure 1) to push the clip stack 28 forward moving the next clip in line 28' through the intermediate position and final position illustrated in Figure 4B. The pusher 24 pushes clip 28' into the delta point 182. The delta point 182 has a ramp surface 184. The top cartridge 20 has a ramp surface 186. The front end or legs 188 of clip 28' engage ramp surface 186. The first contact is made between legs 188 and ramp surface 186. After this first contact is made, the next clip in line 28' is rotated slightly before the inner apex 190 (see Figure 1) of clip 28' contacts sloped surface 184. The next step as illustrated in Figure 4C where the clip 28' is now in position to be fed between crimping members 58 and 60. The next step as shown in Figure 4D where the feeder 30 is pushing the clip 28' distally. The next step is illustrated in Figure 4E where clip 28' enters between crimping members 58 and 60.

Referring now to Figure 1, it will be seen that the cartridge floor 34 has a flexible distal segment 192. The flexibility of the cartridge floor 34 gives the clip 28' the ability to rotate into approximately a 15° angle. Figure 4F indicates the position shown in Figures 4A-4F with clip 28' now ready for application.

To obtain the motions previously described with reference to Figure 4, Figures 1, 2A-2C, and 9 must be reviewed. The same sequence occurs if extension 12 is mounted to actuator 14. Moving the trigger 118 from the open position of Figure 9 into the closed position of Figure 10 advances rod 136 which, in turn, advances rod 148, which provides a distal pushing force on closure member 52. Closure member 52 begins to move distally. As a result of such distal movement, shoulder 106 (see Figures 2A-2C) of closure member 52 (or first member) engages shoulder 102 on rack 84 (see Figure 1). Thereafter, closure member 52 and idler rack 84 move in tandem. As the idler rack 84 advances, it

rotates lower gear 80 (a part of the rotating assembly) as a result of the engagement of gear 80 with teeth 86 on idler rack 84. Gear 76 then rotates through the connection between upper gear 78 and teeth 82 on feeder 30 (or second member), causing feeder 30 to move in the proximal direction, as seen by comparing Figures 4A to 4B. Simultaneously, while the feeder is being retracted, the closure member 52 is advancing toward tapered surfaces 54. The clip 28, which was between jaws 58 and 60 is crimped as jaws 58 and 60 move toward each other when distal end 50 of closure member 52 advances against ramped surfaces 54 pushing them together. It should be noted that the feeder 30 has retracted sufficiently out of position between crimping members 58 and 60 before members 58 and 60 start moving toward each other. The sequence of these movements can be facilitated by selective placement and angularity of ramp surfaces 54 on jaw 46.

As has been explained, the operation of actuator 14 results in crimping of clip 28 as closure member 52 advances distally over jaw 46. As this is occurring, the idler rack 84 moves distally as well, allowing finger 90 to snap over tab 92, as shown in Figures 2A-2B, by comparing the first and second positions. With the closure member 52 fully advanced distally, the trigger 118 can be released. Spring 62 urges closure member 52 proximally allowing the crimping members 58 and 60 to spread apart. Idler rack 84 moves proximally with closure member 52 in the proximal direction until finger 90 abuts tab 92. At that point, closure member 52 can continue to move proximally due to notched area 98 being longer than the distance between shoulders 100 and 102 of idler rack 84. However, once the finger 90 hits tab 92, idler rack 84 is immobilized preventing any further distal movement of the feeder 30. The closure member 52 continues to move proximally until tab 94 engages finger 90, as shown in Figure 2C. The continuing proximal movement of closure member 52 forces finger 90 around tab 92. When this occurs, spring 96 vigorously pulls idler rack 84 proximally until shoulder 102 contacts shoulder 106 on the closure member 52 (see Figure 1). The sudden proximal movement of idler rack 84 turns gear 76 vigorously resulting in rapid distal movement of feeder 30, as illustrated in Figure 4D-4F. At that point, the next clip 28' is ready for application. The purpose of temporarily immobilizing idler rack 84 is to allow the closure member to retreat proximally a sufficient amount to allow the crimping members 58 and 60 to spread sufficiently before the feeder 30 advances the next clip 28' to position between crimping members 58 and 60. Without such a delay, a possibility of jamming could exist if the feeder 30 advances the next clip 28' prior to the crimping members 58 and 60 having had an opportunity to spread far enough to accept the next clip 28'.

Figure 11 illustrates a stapler 10' which can be connected to the actuator 14 or the extension member 12 in the manner previously described. In the embodiment illustrated in Figures 11A-11C, an L shaped slot 110' is used in the manner previously described. A feeder 30' is

mounted for reciprocal movement within a top cartridge housing 20' and a bottom housing 18'. A return spring 194 is mounted to the bottom housing 18' and bears on tab 196 to bias the feeder 30' in the proximal direction. The feeder 30' is actuated in a distal direction by using an actuator 14, which causes rod 136 to contact the feeder 30' in the manner previously described to move the feeder 30' distally advancing a staple 198 toward anvil 200. The staple 198 is formed around anvil 200 due to the advancement of feeder 30'. Upon release of the trigger 118, spring 194 pushes proximally on tab 196 which causes feeder 30' to move proximally. At that point, pusher 202 pushes the next staple in line downwardly into the forming path so that upon subsequent distal movement of feeder 30', the entire process is repeated.

Claims

1. A surgical instrument assembly comprising:
 - an actuating member formed to be grasped by hand; and
 - an instrument having a body;
 - said actuating member having a housing which accepts an end of said instrument body.
2. The assembly of claim 1 wherein:
 - securing means is provided on said body and said housing selectively engageable to prevent accidental disconnection during a surgical procedure;
 - said housing comprises an extending member;
 - said body comprises a receiving member; and
 - said housing further comprises a locking member that selectively traps said extending member to said receiving member.
3. The assembly of claim 2 wherein:
 - said extending member comprises at least one pin;
 - said receiving member comprises at least one slot;
 - said locking member comprises a slide which selectively extends into said slot to secure said pin to said slot; and
 - biasing means is provided to selectively move said slide.
4. The assembly of claim 3 wherein:
 - said slot comprises an opening to accept said pin; and
 - said slide is circumferentially offset from said pin;
 - whereby insertion of said opening over said pin displaces said slide and compresses said biasing means; and

whereby rotation of said body advances said pin further into said slot and presents said opening in alignment with said slide to allow said slide to be biased into said opening to secure the connection.

5

5. The assembly of claim 4 wherein:

said housing comprises a sliding cuff to selectively remove said slide from said opening to facilitate disconnection of said actuating member from said instrument.

10

6. The assembly of any one of claims 1 to 5 wherein:

said actuating member creates a longitudinal force responsive to hand operation;

said instrument body further comprises:

15

at least a first and second movable member; said force being applied by said actuating means to at least one of said first and second members; and means on said body responsive to said applied force and operably connectd to said first and second movable members for causing relative movement therebetween to accomplish a procedure using said instrument.

20

25

7. The assembly of claim 6 wherein:

said first and second movable members are selectively urged to move in opposite directions by said means for causing relative movement.

30

8. The assembly of any preceding claim wherein:

said body contains at least one removably mounted extension segment;

said body components connectable to each other at one end thereof to form a joint by virtue of interaction between an extending member mating with a receiving member and a locking member to selectively trap said extending member in said receiving member to form said joint.

35

40

9. The assembly of claim 8 wherein:

said housing comprises an actuating rod responsive to hand operation of said actuating member;

45

said actuating rod extending into said extension segment;

said extension segment comprising an extension rod in alignment with said actuating rod to transfer motion of said actuating rod to said body for operation of said instrument.
